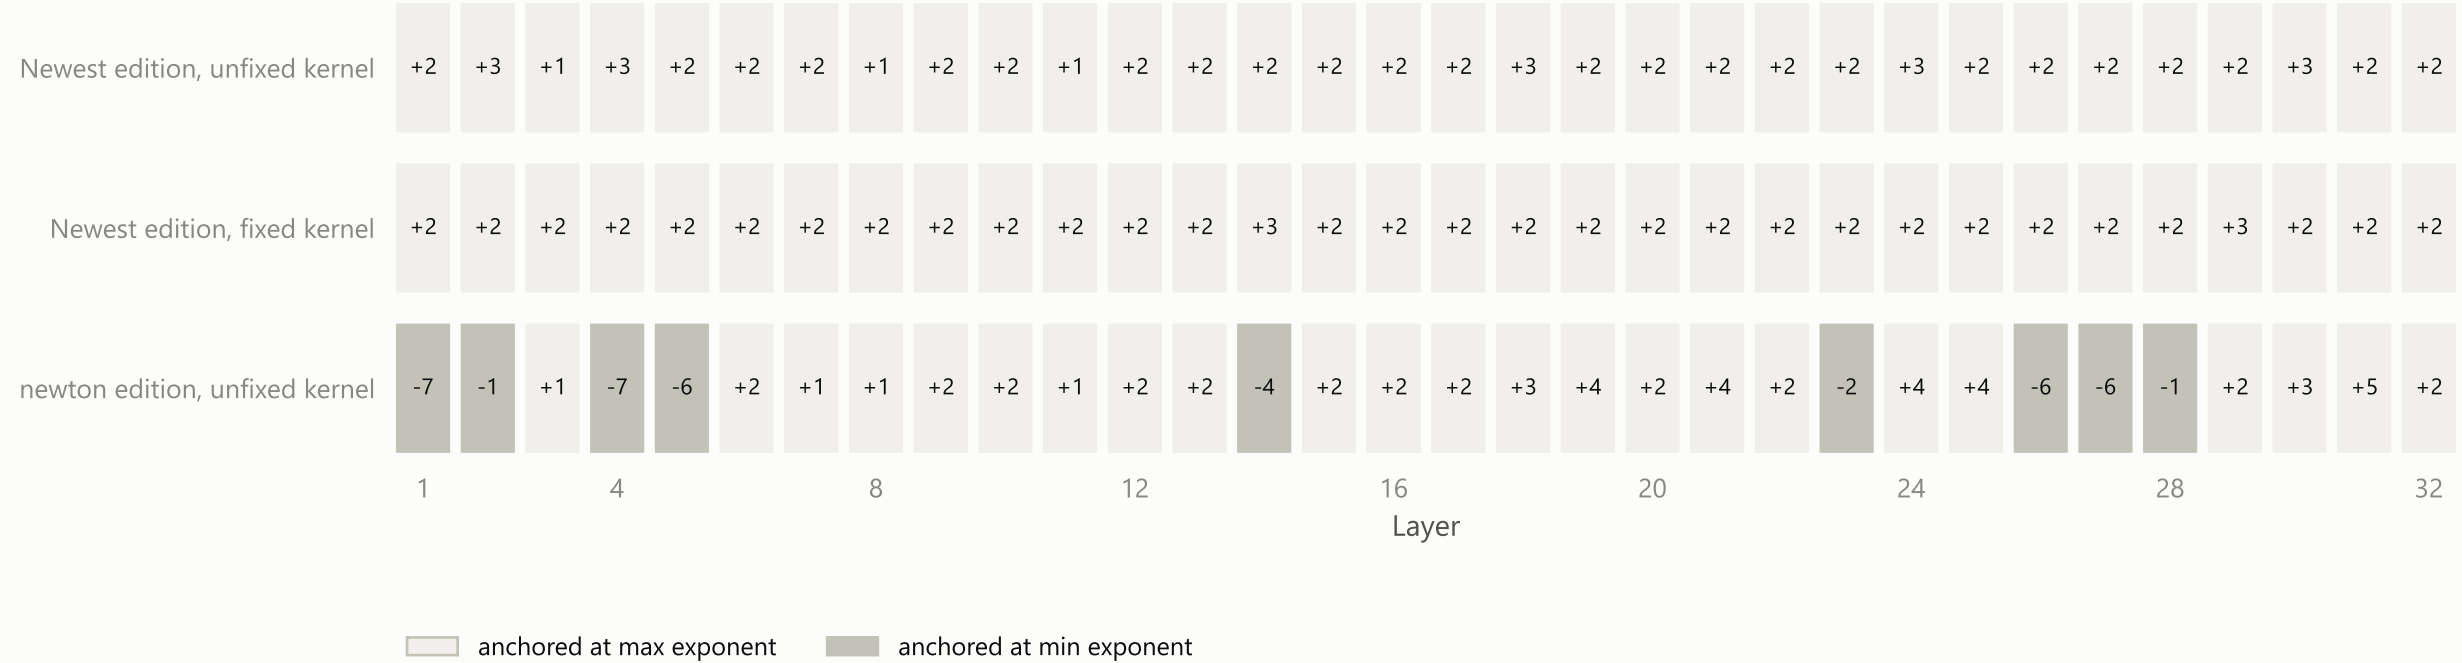
Window chosen at each layer

Question: which LUT window did each search settle on at each layer?
Shows: on the fixed kernel the search kept the starting window (max +2) at 30 of 32 layers; the newton edition, on the unfixed kernel, moved 20 of 32 away from it.



Number = the anchor exponent: the LUT's top exponent when anchored at max, its bottom exponent when anchored at min. The Newest edition's LUT holds 10 exponents, the newton edition's 16 (both slide an 8-wide window inside it), so the same number is not the same window across editions.
